

Leslie Matrices

A certain species of rat has a maximum life span of three years. The probability of a rat surviving its first year is 50% and the probability of surviving its second year is 60%. On average, each rat in its first year produces 0.6 offspring, rats in their second year produce 2.4 offspring each and rats in their third year produce 0.5 offspring each.

The number of rats at initially are 55, 32, 25 for first, second and third year rats respectively.

Write a matrix that will help determine the number of rats after the first year.
